# Relevance Feedback

- Relevance feedback: user feedback on relevance of docs in initial set of results
  - ✓ User issues a (short, simple) query
  - ✓ The **user** marks some results as relevant or non-relevant
  - ✓ The **system** computes a better representation of the information need based on feedback
  - ✓ Relevance feedback can go through one or more iterations
- **Idea:** it may be difficult to formulate a good query when you don't know the collection well, so iterate.

# Relevance Feedback

- The process of query modification is commonly referred as
  - ✓ **relevance feedback**, when the user provides information on relevant documents to a query, or
  - ✓ **query expansion**, when information related to the query is used to expand it
- We refer to both of them as feedback methods
- Two basic approaches of feedback methods:
  - ✓ **explicit feedback**, in which the information for query reformulation is provided directly by the users
  - ✓ **implicit feedback**, in which the information for query reformulation is implicitly derived by the system

# Example: search images

# Key concept: Centroid

- The **centroid** is the center of mass of a set of points
- Recall that we represent documents as points in a high-dimensional space
- Definition: Centroid

$$\vec{\mu}(C) = \frac{1}{|C|} \sum_{d \in C} \vec{d}$$

where  $C$  is a set of documents.

# Example

➡ The centroid is not normalized

# Rocchio Algorithm

- Let us define terminology regarding the processing of a given query  $q$ , as follows:
  - ✓  $D_r$ : set of *relevant* documents among the documents retrieved
  - ✓  $N_r$ : number of documents in set  $D_r$
  - ✓  $D_n$ : set of *non-relevant* documents among the documents retrieved
  - ✓  $N_n$ : number of documents in set  $D_n$
  - ✓  $C_r$ : set of relevant docs among all documents in the collection
  - ✓  $N$ : number of documents in the collection
  - ✓  $\alpha, \beta, \gamma$ : tuning constants

# Rocchio Algorithm

- The Rocchio algorithm uses the vector space model to pick a relevance feedback query
- Tries to separate docs marked relevant and non-relevant – the solution is:

$$\vec{q}_{opt} = \frac{1}{|C_r|} \sum_{\vec{d}_j \in C_r} \vec{d}_j - \frac{1}{N - |C_r|} \sum_{\vec{d}_j \notin C_r} \vec{d}_j$$

- Problem: we don't know the truly relevant docs ( $C_r$ ).

# Rocchio Algorithm

- $C_r$  is not known a priori
- To solve this problem, we can formulate an initial query and to incrementally change the initial query vector

(a)

(b)

# Rocchio 1971 Algorithm (SMART)

- Used in practice:

$$\vec{q}_m = \alpha \vec{q}_0 + \frac{\beta}{N_r} \sum_{\vec{d}_j \in D_r} \vec{d}_j - \frac{\gamma}{N_n} \sum_{\vec{d}_j \in D_n} \vec{d}_j$$

- $D_r$  = set of known relevant doc vectors
- $D_n$  = set of known irrelevant doc vectors
  - ✓ These are different from  $C_r$ !
- $q_m$  = modified query vector;  $q_0$  = original query vector;  $\alpha, \beta, \gamma$ : weights (hand-chosen or set empirically)
- New query moves toward relevant documents and away from irrelevant documents.

# Relevance feedback on initial query

# Subtleties to note

- Tradeoff  $\alpha$  vs.  $\beta$  and  $\gamma$ : If we have a lot of judged documents, we want a higher  $\beta$  and  $\gamma$
- Some weights in query vector can go negative:
  - ✓ Negative term weights are ignored (set to 0)
- **Positive** feedback is **more valuable** than **negative** feedback (so, set  $\gamma < \beta$ ; e.g.  $\gamma = 0.25$ ,  $\beta = 0.75$ ) - many systems only allow positive feedback ( $\gamma=0$ )
- Relevance feedback can improve recall and precision

# Relevance Feedback: Problems

- Long queries are inefficient for typical IR engine
  - ✓ Long response times for user
  - ✓ High cost for retrieval system
  - ✓ Partial solution:
    - Only reweight certain prominent terms - perhaps top 20 by term frequency
- Users are often reluctant to provide explicit feedback
- It's often harder to understand why a particular document was retrieved after applying relevance feedback
- Information needs may change during the interaction (so what?).

# Evaluation of relevance feedback strategies

- Use  $q_0$  and compute precision and recall graph
- Use  $q_m$  and compute precision recall graph
  - ✓ 1) Assess on all documents in the collection
    - Spectacular improvements, but ... it's cheating!
    - Known relevant documents ranked higher
    - Must evaluate with respect to documents not seen by user
  - ✓ 2) Use documents in residual collection (all docs minus those assessed relevant)
    - Measures usually lower than for original query
    - But a more realistic evaluation
    - Relative performance can be validly compared
- Empirically, one round of relevance feedback is often very useful - two rounds is sometimes marginally useful.

# Evaluation of relevance feedback

- Most satisfactory – use two collections each with their own relevance assessments (i.e., split randomly the collection in two parts)
  - ✓  $q_0$  and user feedback from first collection
  - ✓  $q_m$  run on second collection and measured.

# Evaluation: Caveat

- True evaluation of usefulness must compare to other methods **taking the same amount of time** – or using similar user effort
- Alternative to relevance feedback: user revises and resubmits query
- Users may prefer revision/resubmission to having to judge relevance of documents
- There is no clear evidence that relevance feedback is the “best use” of the user’s time.

# Relevance Feedback on the Web

- Some search engines offer a **similar/related** pages feature (this is a trivial form of relevance feedback)
  - ✓ Google (link-based)
  - ✓ Altavista
  - ✓ Stanford WebBase
- But some don't because it's hard to explain to average user:
  - ✓ Alltheweb, msn live.com, Yahoo
- Excite initially had true relevance feedback, but abandoned it due to lack of use.

# Pseudo relevance feedback

- Pseudo-relevance feedback automates the “manual” part of true relevance feedback
- Pseudo-relevance algorithm:
  - ✓ Retrieve a ranked list of hits for the user’s query
  - ✓ Assume that the top k documents are relevant
  - ✓ Do relevance feedback (e.g., Rocchio)
- Works very well on average
- But can go horribly wrong for some queries: e.g. if the top results of a query are all about a subtopic
- Several iterations can cause query drift
- Why?

# Indirect relevance feedback

- Ranked higher documents that users look at more often
  - ✓ Clicked on links are assumed likely to be relevant
    - Assuming the displayed summaries are good, etc.
- Globally: not necessarily user or query specific
  - ✓ This is the general area of clickstream mining
- Today – handled as part of machine-learned ranking.

# Query Expansion

- In relevance feedback, users give additional input (relevant/non-relevant) on **documents**, which is used to reweight terms in the query for documents
- In **query expansion**, users give additional input (good/bad search term) on **words or phrases**.

**YAHOO!**

# How do we augment the user query?

- Manual thesaurus
  - ✓ E.g. MedLine: **physician**, syn: *doc, doctor, MD, medico*
  - ✓ Can be related queries rather than just synonyms
- **Global Analysis:** static; based on all documents in collection
  - ✓ Automatically derived thesaurus
    - co-occurrence statistics
  - ✓ Refinements based on query log mining
    - Common on the web
- **Local Analysis:** dynamic
  - ✓ Analysis of documents in **result set**

# Example of manual thesaurus

# Thesaurus-based query expansion

- For each term,  $t$ , in a query, expand the query with synonyms and related words of  $t$  from the thesaurus
  - ✓ feline → feline cat
- May weight added terms less than original query terms
- **Generally increases recall**
- Widely used in many science/engineering fields
- May significantly decrease precision, particularly with ambiguous terms
  - ✓ “interest rate” → “interest rate fascinate evaluate”
- There is a high cost of manually producing a thesaurus
  - ✓ And for updating it for scientific changes.

# Query assist

- Generally done by query log mining
- Recommend frequent recent queries that contain partial string typed by user
- A ranking problem! View each prior query as a doc – Rank-order those matching partial string ...
